ABSTRACT

Purpose: This study was carried out to assess the effects of the aqueous extract of *Hyptis pectinata* leaves on liver regeneration and on serum enzymes (AST, ALT and γ -GT) after 67% partial hepatectomy in rats. **Methods:** AST, ALT and γ -GT, were determined by conventional procedures using a spectrophotometer (Model E2250-CELM). Liver regeneration was evaluated by immunohistochemical staining for proliferating cell nuclear antigen (PCNA). **Results:** Oral pretreatment during 4 days at 100 mg/kg increased liver regeneration index. At 200 mg/kg, AST level was statistically decreased in comparison to the group submitted to distilled water administration. The other enzymes assessed disclosed no difference when all groups were compared. **Conclusion:** The present study shows that the aqueous extract of *Hyptis pectinata* leaves contains some biological active principles that stimulate liver regeneration at 100 mg/kg and cause slight hepatic protection at 200 mg/kg.

Key words: Liver Regeneration. Partial Hepatectomy. *Hyptis pectinata*. Plant.

RESUMO

Objetivo: Este estudo foi realizado com o objetivo de verificar o efeito do extrato aquoso da *Hyptis pectinata* na regeneração hepática bem como nos níveis das enzimas séricas (AST, ALT e γ -GT) após hepatectomia parcial de 67% em ratos.

Métodos: AST, ALT e γ -GT, foram determinadas pelo método cinético utilizando um espectrofotômetro (Modelo E2250-CELM). A regeneração hepática foi avaliada por imunohistoquímica (PCNA). **Resultados:** O pré-tratamento oral de 100 mg/kg foi realizado durante 4 dias e causou aumento na regeneração hepática. O pré-tratamento oral com 200 mg/kg diminuiu significativamente os níveis de AST quando comparado com o grupo submetido ao pré-tratamento com água destilada. As demais enzimas avaliadas não apresentaram diferenças quando comparadas entre os grupos estudados. **Conclusão:** O presente estudo mostra que o extrato aquoso da *Hyptis pectinata*, numa concentração de 100 mg/kg possui alguma atividade biológica estimulando a regeneração hepática e causando também um leve efeito hepatoprotetor numa concentração de 200 mg/kg.

Descritores: Regeneração Hepática. Hepatectomia Parcial. *Hyptis pectinata*. Planta.

Introduction

Hyptis pectinata (L.) Poit (Lamiaceae), popularly known in Brazil as “sambacaitá” or “canudinho”, is a herbaceous plant with opposing crossed, whole and aromatic leaves. Its flowers are small, clustered into axillary inflorescences, hermaphrodite, pentamer, strongly zygomorphous and bilabiate. It is popularly used to treat rhinopharyngitis, nasal congestion, certain skin diseases, gastric disorders, fever and bacterial infections^{1,2}. In the state of Sergipe, it has been recommended for the treatment of inflammation, pain, cancer, bacterial infections and wound healing³. In experimental studies it has been disclosed that the aqueous extract of *Hyptis pectinata* leaves protects the liver function⁴ and has antinociceptive and antiedematogenic effects³. The essential oil of the plant contains 33 compounds². Monoterpene s are the most common (95,8%). The main constituents are *p*-cymene, thymol and α -terpinene. Together, they correspond to 68% of the total. The presence of thymol is considered the main factor for the antiseptic property of this plant. Considering that there are no studies defining the effects of this plant on liver, this research aimed at assessing the effects of *Hyptis pectinata* leaves on liver regeneration after 67% partial hepatectomy in rats.

Methods

- *Plant material and preparation of the aqueous extract* – *Hyptis pectinata* leaves (identified by Dr C. Dias Silva Jr.; voucher no. ASE 2626, deposited in the Department of Biology of Universidade Federal de Sergipe) were collected outside the blossoming period from the Live Pharmacy of Aracaju, Brazil. The leaves were dried in an oven with air renewal and circulation (model MA-037) at 37° C until complete dehydration. Dried *Hyptis pectinata* leaves were triturated in a blender until a finely granulated powder was obtained. The extract was got from this powder (100 g) by adding distilled water (3:10 w/v) under constant shaking for 4 h at 35° C, followed by filtration (pH 6.0). The filtrate was lyophilized (aqueous extract) and stored at 5° C, yielding 16.2 g (16.2%) of lyophilized active material. At the time of use, the extract was resuspended in distilled water at the desired concentrations.

- *Animals* – The study was carried out on 22 male Wistar albino rats (180 to 230 g). They were fed with a standard pellet diet and water *ad libitum*. All animals were randomly assigned to 4 groups, which consisted of 5 or 7 rats each. During four days, animals from Control, PH100, PH200 and PH400 groups underwent partial hepatectomy and oral administration of distilled water, 100, 200 and 400 mg/kg of the aqueous extract of *Hyptis pectinata*, respectively. On the fourth day of water and plant extract administration (once daily), partial hepatectomy was performed.

- *Surgical procedure* – All operations were performed under ether anesthesia. They always happened at the same time in order to avoid the influence of the changes of circadian cycle. The median and left lateral lobes of the liver (corresponding to 67% of the

organ) were excised⁵. After surgery, the rats were on a normal diet for the whole experimental period. Twenty four hours later, they underwent a new operation to remove the remaining liver. Then, they were sacrificed.

- *Serum enzymes* – Blood samples (4ml) were placed in container without previous anticoagulant treatment. Aspartate aminotransferase, alanine aminotransferase and gamma-glutamyl transpeptidase activities in serum (AST, ALT and γ -GT, respectively) were determined by conventional procedures using a commercial spectrophotometer (Model E2250-CELM).

- *Liver regeneration analysis* – Liver regeneration was evaluated by immunohistochemical staining for proliferating cell nuclear antigen (PCNA) using monoclonal primary anti-PCNA antibody (PC-10; DAKO A/S, Glostrup, Denmark) on formalin-fixed and paraffin-embedded liver tissues^{12,14}. Sections were cut at 4 μ m, mounted on poly-L-lysine-coated glass slides, deparaffinized, rehydrated in an increasing alcohol series, placed in PBS, and treated with 2% hydrogen peroxide in methanol for 15 min to block endogenous peroxidase activity. Nonspecific protein binding was blocked by preincubation with 5% normal horse serum diluted in PBS for 30 min. This was followed by incubation with PC-10 monoclonal primary antibody, diluted 1:40 in PBS for 120 min at 25°C. The sections were then incubated for 35 min with a biotinylated horse antimouse immunoglobulin. The reaction product was detected with an avidin-biotin-peroxidase complex and diaminobenzidine was used as a chromogen substrate. Positive and negative controls were used to assess and control the staining procedure. Sections were examined blindly at high power (400X), and 20 fields were chosen at random. Nuclear labeling indices for PCNA (positive nuclei/total number of counted nuclei) were determined by evaluation of at least 1,000 hepatocyte nuclei.

- *Statistical analysis of data* – The results were reported as means and standard error of mean (SEM). Mann-Whitney's test was used to compare the results between the groups, with the level of significance set to 5%.

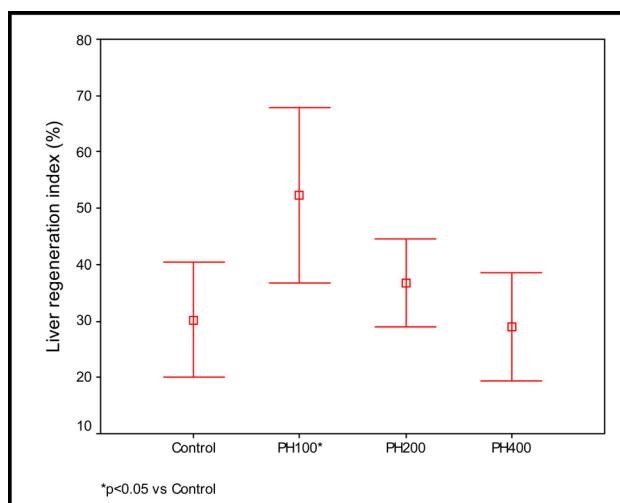

Results

As presented in Figure 1, liver regeneration index was increased in PH100 Group in comparison to Control Group ($p<0.05$). Data from PH200 and PH400 Groups did not disclose statistically significant difference when compared to Control Group. Concerning with serum levels of γ -GT and ALT, there was no statistical significance when all groups were compared. On the other hand, AST level was statistically decreased in PH200 Group in comparison to Control Group ($p<0.05$). The other data were not statistically significant (Table 1).

TABLE 1 - Data showed as means and standard error of mean of serum ALT, AST and γ -GT levels in the absence and in the presence of different concentrations of the aqueous extract of *Hyptis pectinata* (100, 200 and 400 mg/kg).

Group	Dose (mg/kg)	n	ALT (IU/l)	AST (IU/l)	γ -GT
Control	-	5	324.6 ± 105.7	582 ± 176.8	26.4 ± 1.8
PH100	100	5	394 ± 51.6	628.5 ± 94.4	29.8 ± 3.9
PH200	200	7	236.7 ± 44.8	335.5 ± 96.9*	28.7 ± 7
PH400	400	5	422 ± 111.8	530.8 ± 104.4	36.6 ± 17.1

*p<0.05 vs. Control

**FIGURE 1** - Data presented as means and standard error of mean of liver regeneration index (%) in the absence and in the presence of different concentrations of the aqueous extract of *Hyptis pectinata* (100, 200 and 400 mg/kg).

Discussion

According to Stephenson⁶, all drugs exert a dose-dependent effect on their targets. However, this process depends on the amount of available receptors and the physical and chemical properties of the substances. This theory is applied to pharmacology. On the other hand, phytotherapy is not fully understood. It is possible that, at some concentrations, certain compounds of the plant extract could act in synergism and cause a significant effect. At lower or higher concentrations, these compounds could be antagonized by different ones. In a recent work performed by our group, it was verified an antiproliferative activity of copaiba oleoresin on liver regeneration in rats⁷. In the present study, liver regeneration was not stimulated at 200 and 400 mg/kg. This might be explained by hepatocellular membrane receptors saturation or a possible blockage of some stage of the metabolic reaction. It may lead to an uncoupled mitochondrial function which is able to cause relative decrease in liver regeneration and function, as verified in the copaiba oleoresin study⁷. Stimulatory and inhibitory effects are also common in biostimulation by light depending on the dose or wave length^{8,9}. This is an important matter whose answer has not yet been fully formulated. The mechanisms previously analyzed are important to understand why liver regeneration index was increased only at 100 mg/kg and AST levels decreased at 200

mg/kg. Serum gamma-glutamyl transpeptidase (γ -GT) has been widely used as an index of liver dysfunction and marker of alcohol intake. It has a physiological role in counteracting oxidative stress by breaking down extracellular glutathione and making its component amino acids available to the cells. Conditions that increase serum γ -GT, such as obstructive liver disease, high alcohol consumption, and use of enzyme-inducing drugs, lead to increased free radical production and the threat of glutathione depletion¹⁰. The fact that there was no alteration in γ -GT values when the plant extract was used means that *Hyptis pectinata* is not toxic to the rat. The presence of aminotransferases in serum may imply that there has been hepatocellular necrosis¹¹. It is usually found that AST and ALT levels are increased after partial hepatectomy. Most likely, this result is caused by traumatic surgical damage to hepatic mass¹². In this experiment, the plant extract at different concentrations did not induce additional damage to the liver remnant. Inversely, it caused reduction in AST levels at 200 mg/kg. This means that the compounds of *Hyptis pectinata* leaves act in synergism to bring about hepatoprotection. In conclusion, our results show, for the first time, that the lyophilized aqueous extract of the leaves of *Hyptis pectinata* causes improvement on liver regeneration index at 100 mg/kg and hepatic protection at 200 mg/kg.
