## Factors associated with the need for a complete denture in one arch or both arches among the elderly population

**Abstract:** This study aimed to identify factors associated with the need for complete dentures in one dental arch or both, among the elderly population. The cross-sectional household study was conducted with a representative sample of elderly people (65 years or older) in the state of São Paulo, Brazil, in 2015. The dependent variable was the need for complete dentures (in one arch or both), and independent variables were socioeconomic and demographic conditions, social capital, self-perception of oral health and access to dental services. Simple and multinomial logistic regression models tested effect measures (p < 0.05). A total of 5,948 elderly people participated. Results indicated that those with greater chances of needing a complete denture in one arch were male (OR = 1.54; CI95%:1.04-2.29), with fewer household goods (OR = 2.25; CI95%:1.50-3.38), lower monthly household income: R\$501-1500 (OR = 3.44; CI95%:1.27-9.35), R\$1501-2500 (OR = 4.11; CI95%:1.50-11.27), R\$2501-4500 (OR = 2.76; CI95%:1.10-6.95), self-reported need for a complete denture (OR = 4.75; CI95%:3.08-7.35),  $\geq 3$  years since last dental appointment (OR = 1.80; CI95%:1.06-3.05), and dissatisfaction with last dental appointment (OR = 1.80; CI95%:1.06-3.05). There were more chances of the need for complete dentures in both arches among older elders (OR = 1.44; CI95%:1.06-1.88), with lower monthly household income: R\$ < 501 (OR = 4.45; CI95%:1.71-11.60), R\$501-1500 (OR = 4.01; CI95%:2.14-7.51), R\$1501-2500 (OR = 2.95; CI95%:1.64–5.32), < 3 years of education (OR = 1.45; CI95%:1.13–1.85), feeling unhappy (OR = 2.74; CI95%:1.35-5.57), self-reported need for a complete denture (OR = 8.48; CI95%:5.75-12.50), dissatisfaction with their mouth  $(OR = 2.38; CI95\%:1.64-3.46), \ge 3$  years since last dental appointment (OR =4.28; CI95%:2.85-6.43), and dissatisfaction with last dental appointment (OR = 4.28; CI95%:2.85-6.43). The several dimensions of the determinants of the need for a complete denture reflect the influence of both demographic and socioeconomic aspects, social capital, self-perception of oral health and access to dental services.

**Keywords:** Oral Health; Tooth Loss; Denture, Complete.

### Introduction

Among the several health areas in Brazil, oral health has not been a priority of health actions and services historically, despite the high prevalence of caries and periodontal disease, the main consequences

of edentulism.<sup>1</sup> Complete tooth loss constitutes a serious public health problem and is responsible for deleterious physical and emotional consequences.<sup>2,3</sup>

According to the National Oral Health Survey (SB Brazil) 2003 and 2010, edentulism is declining in Brazil among adolescents and middle-aged adults, but the situation remains precarious for the older adult and elderly population.<sup>4</sup> Although the need for prosthetic rehabilitation has seen a substantial decrease for young adults, it will continue to increase for the elderly in the next decades.<sup>45</sup>

Edentulism affects elderly people more,<sup>5</sup> and is undeniable in Brazil's aging population<sup>6</sup>, bearing in mind that the elderly population is expected to increase from 12.6% to 25.1% from 2013 to 2025.<sup>7</sup> Therefore, it is critical to understand the process of population aging, and the impacts that it has on life and health conditions. In this respect, oral health actions should be viewed more in line with reality.

Most studies in the literature have analyzed the use of dental prostheses jointly with its need, or have not distinguished among the types of prostheses analyzed. <sup>8,9</sup> In view of the foregoing, the present study has an original scope, since it sought to analyze the factors associated with the need for a prosthesis, considering a complete denture in one dental arch or both. Therefore, the objective this study was to identify the factors associated with this need for a complete denture in one dental arch or both among the elderly population.

## Methodology

#### Study design and ethical aspects

The cross-sectional study was conducted in the state of São Paulo in 2015 (SB São Paulo) and had the approval of the Research Ethics Committee of FOP-UNICAMP, protocol 094/2015.

#### Sample

The SB São Paulo study is population-based survey, and was conducted in the state of São Paulo, Brazil, in 2015, for the purpose studying the oral health conditions of the over 65-year elderly population.<sup>10</sup>

The sample was designed as a conglomerate in two stages, with probability proportional to population

size (PPP), considering the sample weight and effect of designs in the respective stages of the design. In the first step, the state of São Paulo was stratified into six regions, which we called "domains." A total of 33 cities were drawn for each domain, which we called Primary Sampling Units (PSUs), except for region 1 (Metropolitan Area of the São Paulo State Capital), for which 12 cities were drawn, plus the capital. In the second stage, two census sectors (Census Sampling Units – CSUs) were drawn for each city drawn, also respecting the PPP in the sectors. Hence, the absolute frequency has not be shown, because it does not represent the true value, only the relative frequency.

Sample size was defined based on frequency estimation, variability to be investigated, and acceptable margin of error. The results of the SB Brazil 2010 survey<sup>11</sup> provided the estimates for the city of São Paulo (Region 1 – Capital and Metropolitan Area of São Paulo) and for southeastern São Paulo (Regions 2 to 6).<sup>10</sup>

In 2015, the state of São Paulo had 41 million inhabitants distributed throughout 645 municipalities, in that the capital concentrated 10 million inhabitants. Accordingly, there were different municipalities with different demographic densities and different human development indexes. The stratification strategy was adopted to improve the precision of the data obtained, by allowing more precise estimates to be provided for each stratum of the population within each domain, which had a defined geopolitical distribution. Thus, independent draws of the domains and weights were performed, and were later included in the data analysis for correction of results. The sampling system scheme is shown in Figure 1.

The sample size was estimated for elders 65 years or older, and the study adopted a design effect (deff) of 2.0, error margin of 8.0%, confidence interval of 95.0%, and a non-response rate of 30.0%. The sample size for the 65 or older age group was 5,948.<sup>10</sup>

#### **Data collection**

The epidemiological examinations and interviews were conducted at the volunteers' home by previously trained and calibrated dentists, using the consensus

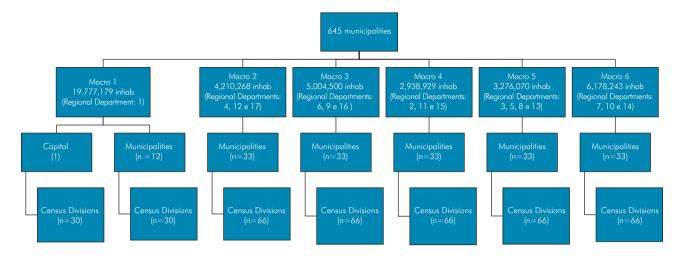

Figure 1. Sample design flowchart.

technique. The minimum accepted kappa value for each examiner and disease studied was 0.652.<sup>10</sup>

The team's calibration process lasted a minimum of 24 working hours, and contemplated the theoretical and practical aspects of the indexes used. The percentage of intra- and interexaminer agreement was measured to establish the reproducibility of the study.<sup>10</sup>

In the SB São Paulo 2015 survey,<sup>10</sup> the oral exams were performed to evaluate the need for dental prosthesis based on the World Health Organization recommendations stated in the 4<sup>th</sup> edition of its Instruction Manual of Basic Epidemiological Surveys in Oral Health, with the adjustments expressed in the SB Brazil 2010 Project.<sup>11</sup> In addition to this, a questionnaire was applied to the individuals examined at their home, which contained questions related to demographic and socioeconomic characterization, self-perception of oral health, social capital and access to dental services.

#### Study variables

The dependent variable was the need for complete denture stratified into one arch or both arches, analyzed for Code 4, which is the need for a dental prosthesis, based on the WHO criteria. The independent variables were divided into four blocks, according to the theoretical model adopted¹² (Figure 2):

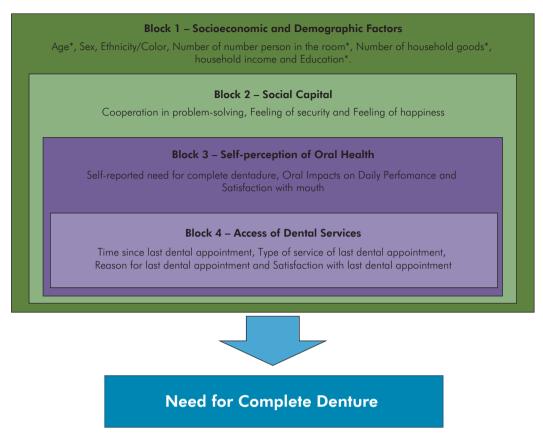

□. Block 1 (demographic and socioeconomic factors): age (< 71 years or ≥ 71 years); sex

(female or male); ethnicity/color (white or not white); number of persons/rooms (< 1 person or  $\geq$  1 person); number of household goods (< 7 household goods or  $\geq$  7 household goods); monthly household income in reals (R\$) ( $\leq$  501, 501 to 1500, 1501 to 2500, 2501 to 4500,  $\geq$  4501) and education (< 3 or  $\geq$  3 years);

- Block 2 (social capital): cooperation in problem-solving (likely, indifferent or unlikely cooperation); feeling of security (secure, regular or insecure); feeling of happiness (happy, indifferent or unhappy);
- c. Block 3 (self-perception of oral health): Need for a complete denture (need or no need); oral impacts on daily performance (OIDP = 0 or OIDP ≥ 1); satisfaction with their mouth (satisfied, regular or dissatisfied);
- d. Block 4 (access to dental services): last dental appointment (< 1 year, 1 to 2 years or ≥ 3 years); type of service of last dental appointment (private health, healthcare insurance or public health service); reason for last dental appointment (routine, pain, extraction or others); satisfaction with last dental appointment (satisfied, regular or dissatisfied).

### Data analysis

The outcome (need or no need for a complete denture in at least one dental arch or in both) was associated with the explanatory variables separated

\*Variable dichotomized by median

Figure 2. Theoretical model adapted for the study.

into 4 blocks, according to the theoretical model adopted. The blocks represented socioeconomic and demographic factors, social capital, self-perception of oral health and access to dental services, respectively (Figure 2). Of these categories, the "no need" condition was used as a reference for the analyses developed. The simple and multinomial logistic regression models were calculated, and the association strength was expressed by the odds ratio (OR) with a confidence interval (CI) of 90.0%.

The data analysis was initially described according to Pearson's chi-square test adjusted using the Rao-Scott correction, considering the complex sample design, with respective weights and sampling strata. After performing the simple analysis, independent variables with p-value < 0.25 were eligible for multilevel analysis, as supported by the literature. The forward method was applied to perform the multilevel model method (p < 0.05).  $^{13}$ 

Several multilevel analyses were performed to determine the multilevel model in each block, starting with the variables belonging to the most distal block, in which they were introduced into the model one by one (forward method), until only the variables statistically associated with the outcome remained (p < 0.05). The same step was repeated for the subsequent level (intermediate and proximal) to analyze the variables of subsequent levels, whereas the variables of the previous level were retained, even though the statistical significance changed.

## **Results**

Data was analyzed on 5,948 individuals aged 65 years or older, representative of the state of São Paulo. Most of the elderly participants were older white women (> 71 years old), with a monthly household income between R\$501–1500, and < 3 years of education (Table 1).

**Table 1.** Description of independent variables according to dependent variable (n = 5,948).

| Variables                            | Need for complete denture |         |             |                    |          |  |  |
|--------------------------------------|---------------------------|---------|-------------|--------------------|----------|--|--|
|                                      | Total                     | No need | In one arch | In both arches (%) | p-value  |  |  |
|                                      | (%)                       | (%)     | (%)         |                    |          |  |  |

<sup>\*</sup>Dichotomized by the median. \*\*With statistically significant difference after adjusting the data (p < 0.05).

In Table 2, following application of the adjusted analysis, there was a greater chance of the need for a complete denture in one arch among males (OR = 1.54; CI95%: 1.04-2.29), with fewer household goods (OR = 2.25; CI95%: 1.50-3.38), low income: R\$501-1500 (OR = 3.44; CI95%: 1.27-9.35), R\$1501-2500 (OR = 4.11; CI95%: 1.50-11.27), R\$2501-4500 (OR = 2.76; CI95%: 1.10-6.95), self-reported need for a complete denture (OR = 4.75; CI95%: 3.08-7.35),  $\geq 3$  years since last dental appointment (OR = 1.80; CI95%: 1.06-3.05), and dissatisfaction

with the last dental appointment (OR = 1.80; CI95%: 1.06-3.05).

In Table 3, following application of the adjusted analysis, there was a greater chance of the need for a complete denture in both arches among older elders (OR = 1.44; CI95%: 1.06-1.88), with low household income: R\$501-1500 (OR = 4.01; CI95%: 2.14-7.51), R\$<501 (OR = 4.45; CI95%: 1.71-11.60), R\$1501-2500 (OR = 2.95; CI95%: 1.64-5.32), < 3 years of education (OR = 1.45; CI95%: 1.13-1.85), self-reported need for a complete denture (OR = 8.48;

**Table 2.** Crude and adjusted analysis of the model of multinomial logistic regression for need for complete denture in one arch among elderly residents in State of São Paulo, Brazil, 2015 (n = 5,948).

## **Discussion**

The results of the present study pointed out the determinants of the need for a complete denture in multiple dimensions; however, analysis of one arch or both arches separately indicated that some factors were different. The analysis performed confirmed

that the criterion should be considered to address this historical problem of lack of dental care in the elderly Brazilian population. The evidence of population aging and the change in the oral epidemiological pattern in Brazil points to the urgent need to prioritize the inclusion of elderly dental needs in the nation's oral health policies, such as oral rehabilitation.

According to data from the SB Brazil 2010 survey, 76.5% of the Brazilian elderly population used a prosthesis, and 63.1% used complete dentures, found to be the most widely used type. Likewise, although the state of São Paulo is the most highly developed state in

**Table 3.** Crude and adjusted analysis of the model of multinomial logistic regression for need for complete denture in both arches among elderly residents in State of São Paulo, Brazil, 2015 (n = 5,948).

<sup>\*</sup>Dichotomized by the median. \*\*With statistically significant difference after adjusting the data (p < 0.05).

the country, the data from this survey indicated that its elderly population presented a high percentage of extracted teeth and great need for dentures, especially complete ones. 10,11

Among the demographic factors associated with the survey, men showed a greater need for prosthesis in only one arch. This aspect may be a direct reflection of the lower motivation to seek dental services and access to them, as well as lower adherence to using a prosthesis among men.<sup>9</sup> In this study, older elderly people had a greater need for a prosthesis in both arches. Although aging has no direct physiological

relationship to tooth loss, the cumulative effect of oral diseases over time leads to edentulism. Aging is also associated with lower adherence to use of a prosthesis over time, commonly because of failures in the preparation, adaptation and/or maintenance of the prosthesis. 16,17

Socioeconomic factors were associated with the need for a complete denture in one arch and/or both, since a population with lower household income, less education, and a below average number of household goods, has a higher chance of the need for upper and lower complete dentures. This finding is corroborated

by Matsuyama,<sup>18</sup> carried out with older people, which demonstrated an association between denture use and economic status, and which leads us to consider that socioeconomic conditions reverberate in the living and health conditions of the population, including oral health.<sup>19</sup> Thus, the economic conditions of a nation's inhabitants, especially those subject to social and political inequities, can adversely influence the living conditions of dwellers.<sup>20</sup>

The decrease in quality of life and its impacts can be expressed by the decrease in chewing ability and phonation, as well as nutritional, psychological and aesthetic losses, and the reduction in self-esteem and social integration,<sup>20</sup> as evidenced by the results found in this study. In the social capital block, elders who were less happy presented a greater need for complete dentures in both dental arches.

In addition, the elders who self-perceived the need to use total prosthesis were associated with both analyses (one arch and both arches). This was also demonstrated in another Brazilian study,9 in which the dissatisfaction with their mouth presented a greater need for complete dentures in both arches. Thus, patients must be rehabilitated regarding function and aesthetics to achieve success in prosthetic treatment. This success further enables patients to enjoy psychological well-being and better general health, thus counteracting the consequences of edentulism. 20,21,22 There is no consensus in the literature about the influence of others factors, such as social, economic, demographic and psychosocial determinants, in the self-perception of oral healthrelated quality of life, thus revealing a low perception of oral health in relation to these factors.<sup>23</sup>

Regarding access to dental services, a longer amount of time since the last dental appointment and dissatisfaction with the last dental appointment were associated with the need for a complete denture in one arch or both. This study showed that access to dental services is still a barrier, especially for the elderly, a population historically excluded from public oral health policies in Brazil. The provision of a total prosthesis is currently contemplated in the National Oral Health Policy, and a considerable number of older people currently wear dentures in Brazil. Data in the literature<sup>4,24</sup> have shown that a

large portion of these dentures must be replaced or repaired. This emphasizes the importance of broadening actions directed toward instituting prosthetic rehabilitation in the Brazilian Unified Health System (SUS). Therefore, the present data analysis based on the SB São Paulo 2015 survey highlights that the National Oral Health Policy must be broadened to include more specific policies for the elderly population, and a more resolute system for making prostheses, such as expanding the supply of total prostheses in primary care.<sup>25</sup> Other actions of intersectional scope must also be integrated and implemented.<sup>19</sup>

Another factor that should be considered as a parameter for the analysis of healthcare service results is patient satisfaction regarding the care received.<sup>26</sup> This user-established measure is a sensitive indicator of the quality of service provided. It can subsidize the planning of health programs and policies, and promote more adequate use of services,<sup>27</sup> although surveys report that some other factors may directly or indirectly influence it, such as sociodemographic factors, health-related factors and attitudes, or subjective factors.<sup>28</sup>

In view of the foregoing, the authors feel that it is important to make the population aware of the need for dentures, particularly regarding the factors that can interfere with preparing health policies that would be coherent with the reality of each region. In this sense, the present study was of unquestionable relevance, because it proposed to analyze a situation based on a theoretical model that considered several sets of variables, despite having the limitation of being cross-sectional. In this type of study, it is difficult to establish causal relationships based on a cross section of time, thus limiting one's confidence in establishing the direction of the association. Moreover, the authors feel that closed questionnaires limit or induce responses, and that some questions depend on the participants' memory. On the other hand, this study had notably strong points, including the use of data from a broadly representative survey, which extended the relevance of the data to other Brazilian states, and other regions and countries with similar characteristics.

## **Conclusion**

The need for a complete denture was associated with several dimensions. In one arch, it was associated with demographic and socioeconomic

aspects, self-perception of oral health and access to dental services, and in both arches, with demographic and socioeconomic aspects, social capital, self-perception of oral health and access to dental services.
