

***Lebiasina yepezi*, a new Lebiasininae (Characiformes: Lebiasinidae) from the Serra Parima-Tapirapecó mountains**

André L. Netto-Ferreira¹, Osvaldo T. Oyakawa¹, Jansen Zuanon² and José C. Nolasco¹

Lebiasina yepezi, a new Lebiasininae with a conspicuous color pattern, is described. The new species is endemic of the headwaters of the rio Negro, rio Branco, and rio Orinoco in the Serra Parima-Tapirapecó Mountains, at the border of Brazil and Venezuela. The new species is readily distinguished from all other Lebiasininae by the presence of four black longitudinal stripes on the trunk, and the triangular shaped dorsal surface of the mesethmoid, lacking lateral projections. The unusual color pattern is contrasted with those of other lebiasinins, as well as members of the pyrrhulinin genus *Nannostomus*. A close relationship between *Lebiasina yepezi* and the Gran Sabana (Venezuela) species is suggested based in color pattern features. The present contribution corresponds to a further refutation of the type locality of *L. intermedia*, as suggested on its description, since Lebiasinins, except *L. bimaculata*, *L. boruca*, and *L. festae*, do not occur in low land waters.

Lebiasina yepezi, um novo Lebiasininae com um conspícuo padrão de colorido, é descrito. A nova espécie é endêmica das cabeceiras do rio Negro, rio Branco e rio Orinoco, na Serra Parima-Tapirapecó, ao longo da fronteira entre Brasil e Venezuela. A nova espécie é prontamente diferenciada das demais espécies pela presença de quatro faixas longitudinais escuras ao longo do corpo, e a superfície dorsal do mesetmoide com o formato triangular, não apresentando projeções laterais. O padrão de colorido incomum é comparado com o dos demais Lebiasininae e também com o dos Pyrrhulininae do gênero *Nannostomus*. Uma próxima relação é proposta entre *Lebiasina yepezi* e as espécies da Gran Sabana (Venezuela) com base em caracteres de colorido. A presente contribuição corresponde a mais uma refutação da localidade-tipo de *L. intermedia* conforme sugerida na descrição daquela espécie, uma vez que os lebiasiníneos, com exceção de *L. bimaculata*, *L. boruca* e *L. festae*, não ocorrem em rios de terras baixas.

Key words: Distribution pattern, Gran Sabana, Guyana Shield, Ostariophysi, Systematics.

Introduction

The Lebiasinidae is a Neotropical characiform family consisting of seven genera distributed in two subfamilies: Lebiasininae (*Lebiasina* Valenciennes, plus *Piabucina* Valenciennes), and Pyrrhulininae (*Pyrrhulina* Valenciennes, *Copeina* Fowler, *Copella* Myers and *Nannostomus* Günther). The monotypic genus *Derhamia* Géry & Zarske was originally assigned to the Lebiasininae (Géry & Zarske, 2002), but it was not placed in either subfamilies by Weitzman & Weitzman (2003), and it is currently considered an *incertae sedis* genus in the Lebiasinidae (Nelson, 2006). The species belonging to the family are small- to medium-sized fishes ranging from the

miniature *Nannostomus anduzei* Fernandez & Weitzman, about 1.6 mm SL, to species of *Lebiasina*, that reach up to 200.0-250.0 mm SL.

The greatest diversity of the family occurs in the Pyrrhulininae, which are distributed primarily in the Amazon and Orinoco basins, and coastal rivers of the Guyana Shield, occurring mainly in shallow waters of forest streams and small ponds along the lower parts of larger rivers. *Pyrrhulina*, the most widespread and speciose genus in the family, is the only one known for the Paraná-Paraguay system (including the rio Uruguay). Species of Lebiasininae, on the other hand, are usually found in the upper courses of streams with rocky or sandy bottoms and well oxygenated

¹Universidade de São Paulo, Museu de Zoologia, P. O. Box 42494, 04218-970 São Paulo, Brazil. alnferreira@gmail.com; oyakawa@usp.br; cezarnolasco@yahoo.com.br

high waters in the rio Amazonas, rio Orinoco and coastal drainages on the Atlantic and Pacific slopes of Colombia, Costa Rica, Ecuador, Guyana, Panama, Peru, and Venezuela. The only exception would be *Lebiasina intermedia* Meinken, presumably from Santarém in the lower Amazon (Géry, 1977; Weitzman & Weitzman, 2003).

Collections in the upper courses of the rio Negro, rio Branco, and rio Orinoco draining from the Serra Parima-Tapirapecó, along the border of Brazil and Venezuela, yielded specimens of a conspicuously patterned new lebiasinin, which is described herein, and its relationships among other Lebiasininae are discussed. The new species is assigned to the genus *Lebiasina* following anterior studies questioning the validity of *Piabucina* (Eigenmann & Allen, 1942; Weitzman, 1964; Machado-Allison, 1974; Dahl, 1971; Géry, 1977; Taphorn, 1992; Géry & Zarske, 2002), or disregarding it (Ardila-Rodríguez, 1994, 1999, 2000, 2001, 2002, 2004, 2008a, 2008b, 2009, 2010), notwithstanding the presence of an adipose fin in most species described.

Material and Methods

Counts and measurements follow Fink & Weitzman (1974) and Menezes & Weitzman (1990). All measurements were made point-to-point on the left side of the specimens whenever possible, with dial calipers with a precision of 0.1 mm. Standard length is presented in mm, all other measurements are presented as proportions of standard length (SL), except for subunits of head, which are presented as proportions of head length (HL). Meristic data are given in the description, followed by the frequency of each count in parenthesis, and an asterisk indicates the value of the holotype. Counts of teeth, vertebrae, supraneurals, and procurent caudal-fin rays were taken only from cleared and double-stained paratypes (c&s), prepared according to Taylor & van Dyke (1985), or x-rayed specimens. Vertebrae of the Weberian apparatus were included as four elements in the precaudal counts, and the fused PU1+U1 of the caudal region as a single element in the caudal counts. Pattern of circuli and radii was observed on scales sampled from the region between the lateral line series and the insertion of the dorsal fin. Color pattern nomenclature follows Weitzman (1966). Institutional abbreviations follow Ferraris (2007), with the addition of CAR (Colección Carlos A. Ardila Rodríguez, Barranquilla, Atlántico, Colombia), IAvH-P (Instituto de Investigación de Recursos Biológicos Alexander von Humboldt, Colección de Peces, Villa de Leyva, Boyacá, Colombia), MAC-PAY (Ministerio de Agricultura y Cría, Instituto Nacional de Investigaciones Agrícolas (INIA), Estación Experimental Amazonas, Puerto Ayacucho, Amazonas, Venezuela), UCR (Universidad de Costa Rica, Escuela de Biología, Museo de Zoología, Departamento de Biología, Colección de Ictiología, San José, Costa Rica) and UF (University of Florida, Florida Museum of Natural History, Gainesville, Florida, USA.). Abbreviations used in the text are: FRO - frontal; LAT - lateral ethmoid; MES - mesethmoid; NAS - nasal; PRE - premaxillary.

Diagnosis. *Lebiasina yepezi* is readily distinguished from all other members of Lebiasininae by the presence of a primary, secondary, tertiary, and intermediate stripes on the sides of the trunk (Fig. 1; vs. primary and secondary stripes present in most Lebiasininae, except: *L. astrigata* (Regan), *L. aureoguttata* (Fowler), *L. chocoensis* Ardila-Rodríguez and *L. multimaculata* Boulenger, which present only the secondary stripe), and dorsal surface of the mesethmoid triangular shaped (Fig. 2), without lateral projections (vs. mesethmoid T-shaped). *Lebiasina yepezi* further differs from its congeners (except *L. taphorni* Ardila-Rodríguez, *L. unitaeniata* (Günther), *L. uruyensis* Fernandez-Yepez, and *L.*

Fig. 1. *Lebiasina yepezi*: **a**) MNRJ 39067 holotype (152.9 mm SL), Brazil, Amazonas, rio Marari, tributary of rio Padauari, Serra Tapirapecó; **b**) MNRJ 38917, paratype (97.5 mm SL), same data as holotype.

yuruaniensis Ardila-Rodríguez) by the secondary stripe extending along scales of second and third longitudinal series (vs. stripe extending along scales of first and second longitudinal series), and caudal-fin blotch restricted to the caudal-fin median rays (vs. anterior margin of caudal-fin blotch extending onto caudal peduncle). The new species also differ from its closest geographical relatives, *L. yepezi* differs from *L. taphorni* Ardila-Rodríguez, *L. unitaeniata* (Günther), *L. uruyensis*, and *L. yuruaniensis* Ardila-Rodríguez by the extent of the intermediate stripe (from infraorbitals to anal-fin origin; vs. intermediate stripe restricted to infraorbitals 2 to 4).

Description. Morphometric data of *Lebiasina yepezi* are presented in Table 1. Body compressed and elongate. Dorsal profile of body distinctly convex from upper lip to vertical through nares, becoming slightly convex from that point to vertical through pectoral-fin origin, then nearly straight from latter to dorsal-fin origin; and slightly concave from that point to dorsal caudal-fin procurrent rays. Ventral profile of head and trunk convex from lower lip to pelvic-fin origin; straight from that point to anal-fin origin, convex at anal fin base, and concave from anal fin terminus to caudal-fin procurrent rays.

Mouth terminal. Premaxillary with single row of 9(1) or 11(1) tricuspid teeth decreasing in size posteriorly. Posterior tip of maxillary reaching distinctly beyond vertical through anterior margin of orbit. Maxillary with 5(1) or 7(1) tricuspid teeth. Dentary with two series of teeth. Outer series with 12(1) or 18(1) pedunculate tricuspid teeth with central cusp

distinctly larger, teeth gradually decreasing in size posteriorly. Inner series with several minute conical teeth extending from the symphysis to coronoid process. Branchiostegal rays 4, 3 articulating with anterior-ceratohyal, and one with posterior-ceratohyal.

Scales cycloid, circuli restricted to posterior border of scales, several radii (approx. 25) converging to center of scales and strongly anastomosed in the center, forming several cells. Lateral line longitudinal series with 26(1), 27(5), 28*(4), or 29(1) scales, of which only 3(3), 4(1), 5*(9), or 6(1) are perforated. Longitudinal rows of scales between dorsal and pelvic fins 7. Predorsal scales 12(7) or 13*(7). First longitudinal row of scales usually reaching vertical through dorsal-fin terminus, but may extend beyond that point by one or two scales. Circumpeduncular scales 12.

Pectoral fin with i,13(1), 14(4), 15*(5), or 16(2) rays. Pelvic fin i,7*. Supraneurals 10(8), anterior to neural spine of centra 5 to 14(8). Dorsal fin ii,8*(8) or 9(4) rays. First dorsal-fin pterygiophore inserted posterior to neural spine of centrum 14(8). Distal margin of extended dorsal fin rounded. Dorsal-fin origin closer to caudal-fin origin than to tip of snout. Base of last dorsal-fin ray anterior to vertical through anal-fin origin. Anal fin iii,8*(9) or 11(1), last ray adnate. Distal border of extended anal fin rounded. First anal-fin pterygiophore inserted posterior to hemal spine of centrum 24(8). Adipose fin present. Caudal fin furcate, with upper lobe distinctly longer than lower lobe; both lobes rounded. Principal caudal-fin rays i,9/8,i. Dorsal procurrent rays 9(2);

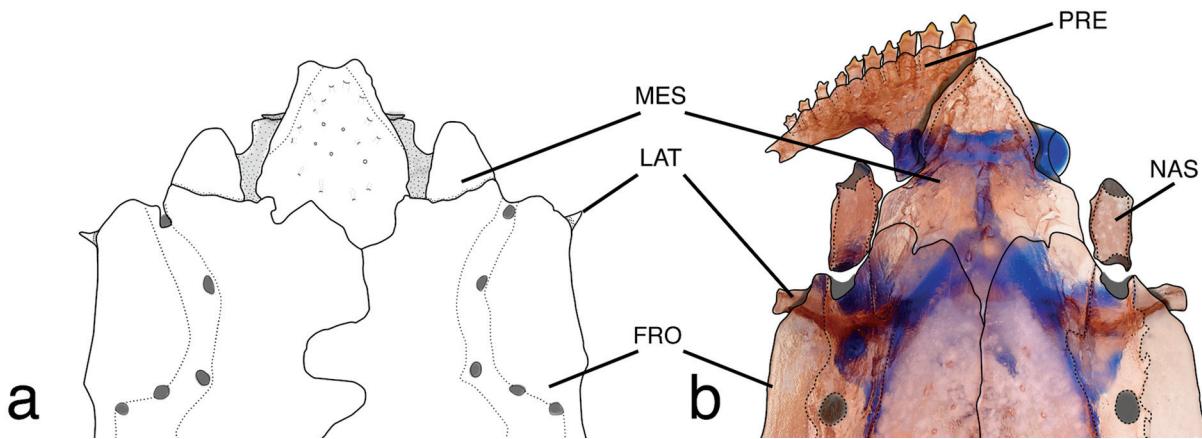

Fig. 2. Anterior portion of the skull in dorsal view of: **a**) *Lebiasina astrigata* (MEPN 4418, 94.5 mm SL); **b**) *Lebiasina yepezi*. (MZUSP 81128, 42.8 mm SL), showing the usual T-shaped mesethmoid of Lebiasininae and the absence of lateral projections, respectively (FRO - frontal; LAT - lateral ethmoid; MES - mesethmoid; NAS - nasal; PRE - premaxillary).

ventral procurrent rays 8(1) or 9(1). Precaudal vertebrae 23(2); caudal vertebrae 19(2).

Color in alcohol. Background color yellowish. Head densely pigmented from upper lip to origin of scales on the mid-posterior portion of parietals. Dark brown pigmentation extending from that point to caudal-fin insertion, through mid-dorsal series of scales and immediately bordering scale rows. Infraorbital bones and opercular series with yellowish background color, with dark portions where primary, secondary and intermediate stripes extend across. Lower lip dark, densely pigmented. Ventral portion of head with minute scattered chromatophores.

Trunk dark dorsally, becoming lighter ventrally from third longitudinal series of scales. Abdominal area yellowish, lacking pigmentation between the isthmus and anal-fin origin. Mid-dorsal series with a black longitudinal stripe from back of head to dorsal-fin origin. Humeral blotch inconspicuous, round, overlapped by primary stripe. Four dark longitudinal stripes on the trunk. Primary stripe conspicuous, originating posterior to eye, extending across infraorbitals four and five, opercle and along trunk, to terminate at rear of caudal peduncle. Stripe subdivided starting at vertical through dorsal-fin terminus, into 10-12 small round blotches, overlying scales of fourth longitudinal series. Secondary stripe inconspicuous, extending from supracleithrum to middle rays of upper caudal-fin lobe, over second and third longitudinal series of scales. Conspicuous intermediate stripe usually extending from mouth to vertical through anal-fin origin, onto scales of fifth longitudinal series, between primary and tertiary stripes. Tertiary stripe densely pigmented, except at proximal portion of caudal peduncle, extending from pectoral-fin origin to middle portion of caudal-fin lower lobe, onto scales of sixth longitudinal series. Caudal-fin blotch diffuse and rounded in juvenile specimens, located at basal portion of five median caudal-fin rays; caudal-fin blotch inconspicuous or absent in

specimens longer than 123.0 mm SL, in which it may be represented by patches of chromatophores. Anterior border of caudal-fin blotch not extending onto caudal peduncle. Pelvic and dorsal fins hyaline, base of pectoral-fin rays densely pigmented, forming a round dark blotch. Anal fin lightly pigmented, grayish, with distal border hyaline. Base of last two anal-fin branched rays densely pigmented, forming an oblong dark blotch. Caudal-fin rays densely pigmented.

Table 1. Morphometric and meristic data for *Lebiasina yepezi*. SD - standard deviation.

Upper jaw length	5.1	12	5.1-10.3	7.0	2.1

Sexual Dimorphism. Mature males of *Lebiasina yepezi* present the most common pattern of sex dimorphism among species of the genus: in which the anal-fin rays and anal-fin base are distinctly longer and thicker than females (Fig. 3); hypertrophy of the inclinator muscles and the spiniform processes in which the muscles attach to the first lepidotrichia; scales of the fifth longitudinal series along the base of the anal fin modified (covered by a thin layer of a spongy, apparently glandular, tissue); and breeding tubercles present on pectoral-, pelvic- and anal-fins rays, as well as on scales and sides of the head.

Distribution. Specimens of *Lebiasina yepezi* are known from rio Parima (rio Mucajá system) and rio Uraricoera in the rio Branco drainage, rio Amazonas system, Roraima State, Brazil, the rio Marari (rio Padauari system) in the rio Negro drainage, rio Amazonas system, Amazonas State, Brazil, and the upper rio Orinoco drainage, upstream of La Esmeralda, Amazonas State, Venezuela (Fig. 4).

Etymology. The specific name honors Agustín Fernández Yépez, first collector of the new species described herein.

Ecological notes. *Lebiasina yepezi* inhabits small and shaded forest streams, with fast-flowing clear water and a substrate consisting mainly of rocks and sand.

Discussion

In his study of the fish fauna near the río Yaracuy in Venezuela, Fernández-Yépez (1972: 13) mentions in passing a species yet to be described from the upper course of the Orinoco. Given that author had collected specimens of *Lebiasina yepezi* in 1951 (MHNLS 797), it is likely that he was referring to this species in his comment. Géry (1977: 588) was the first to depict the new species in a photo by Axelrod of a juvenile specimen collected at the Parima mountains in northern Brazil, which is currently cataloged as USNM 306560. In the occasion, Géry listed it as an unidentified characiform, “possibly near *Nannostomus* or *Pyrrhulina*”. Subsequently, Géry & Zarske (2002: 44-45) proposed a possible relationship between this species and *Derhamia hoffmannorum*, based on their conception of the relationships of the lebiasinid genera, but the authors did not provide evidence to such a hypothesis. In two phylogenetic studies based on morphologic data of the family Lebiasinidae, Netto-Ferreira (2006, 2010) refuted this hypothesis, proposing *L. yepezi* as being more closely related to the Lebiasinins from the Guyana Shield than *Derhamia*. Such close relationship between *Lebiasina yepezi* and its congeners from the Gran Sabana, Venezuela, *L. taphorni*, *L. unitaeniata*, *L. uruyensis*, and *L. yuruaniensis* (fig. 4) is supported by: first longitudinal series of scales short, ending near the dorsal-fin terminus; posteriorly displaced caudal blotch, not located on the caudal peduncle; secondary stripe passing onto the scales of the second and third longitudinal rows of scales; and the presence

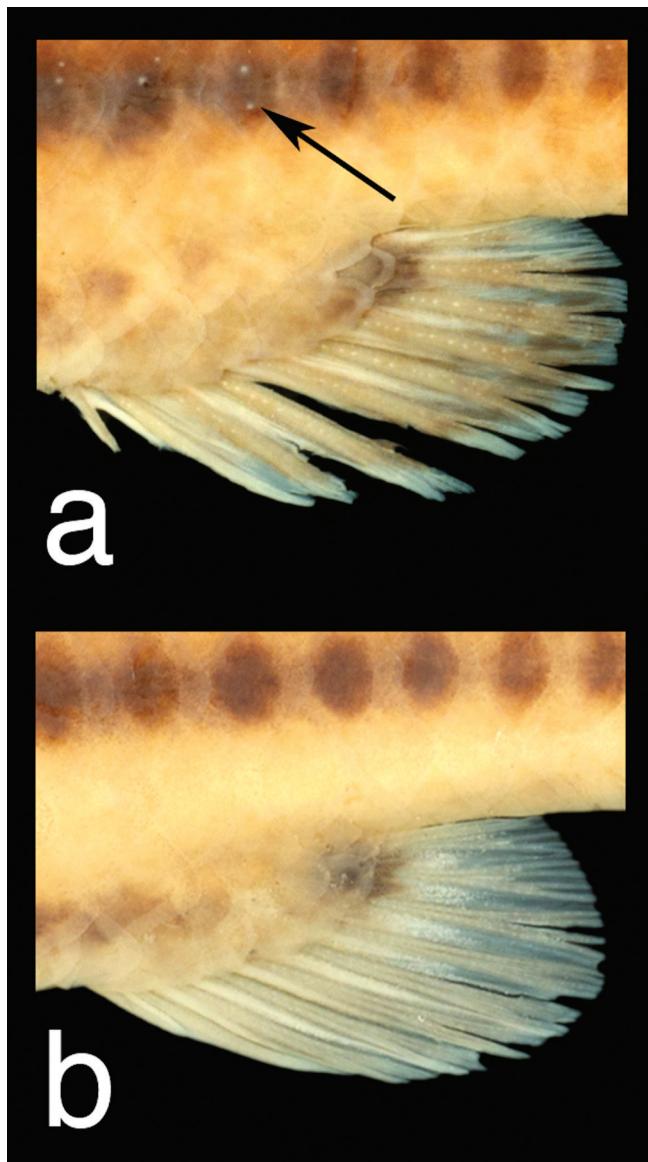

Fig. 3. Anal-fin of *Lebiasina yepezi* evidencing the sexual dimorphism: **a**) Male (MNRJ 39067 - holotype) 152.9 mm SL; **b**) female (MNRJ 38917 - paratype) 97.5 mm SL. Arrow indicates breeding tubercles on the scales.

of the intermediate stripe, passing at least onto third infraorbital, usually represented by a horizontally elongate blotch (which in few specimens of *L. uruyensis* may form an inconspicuous stripe, passing onto the scales of the fifth longitudinal series in a way similar to that in *L. yepezi*).

The presence of multiple dark longitudinal stripes along the body is an unusual color pattern among the Lebiasininae, albeit common among species of the Pyrrhulininae genus *Nannostomus* (three stripes present in *N. limatus* Weitzman, *N. marginatus* Eigenmann, *N. marilynae* Weitzman & Cobb, *N. minimus* Eigenmann, *N. mortenthaleri* Paepke & Arendt, *N. rubrocaudatus* Zarske, and *N. trifasciatus* Steindachner;

Fig. 4. Map of northern portion of South America with the distribution of Guyana Shield species of Lebiasininae: *Lebiasina yepezi* (stars), *L. unitaeniata* (diamonds), *L. uruyensis* (squares), *L. taphorni* (triangle) and *L. yuruaniensis* (circles). White polygons represent type-localities.

four stripes in *N. britskii* Weitzman and *N. eques* Steindachner). Young specimens of *Lebiasina yepezi* can be distinguished from these species of *Nannostomus* with a somewhat comparable color pattern by the broader and slightly upturned mouth and the presence of tricuspidate teeth (vs. a narrow terminal mouth with spatulate multicuspidae teeth in *Nannostomus*).

Lebiasina yepezi represents an additional species inhabiting both the rio Negro and rio Orinoco drainages. The continuous discovery of new species restricted to the headwaters of rivers draining from the Guyana Shield (Fernández-Yépez, 1967; Ardila-Rodríguez, 1999, 2000, 2004) suggests that the diversity of the Lebiasininae in that area still needs further investigation. Ongoing revisionary studies conducted by the senior author revealed three new lebiasinins occurring in the headwaters of the rio Mazaruni and the rio Potaro (a drainage exhaustively sampled by Eigenmann in the early 20th century) in the Guyana Shield.

Additionally, three new species have also been discovered in the headwaters of rio Xingu and rio Tapajós, in the Brazilian Shield, an area where lebiasinins were not expected to occur. The apparent peripheric distribution of these species in the

upper portions of the rio Amazonas and the rio Orinoco systems represent further evidence that, with exception of *Lebiasina bimaculata*, *L. boruca*, and *L. festae*, species of Lebiasininae do not inhabit low land waters, living exclusively in fast flowing clear headwaters. Therefore, Meinken's suggestion that the type locality of *L. intermedia*, "near Santarém" is most likely inaccurate as suggested by Géry (1977) and Weitzman & Weitzman (2003). So far, any recent collection yielded specimens comparable with that described by Meinken, and it is likely that specimens of *L. intermedia* are still awaiting to be rediscovered in either Guyana or Brazilian Shields.
